# 1 Complex numbers

## 1.1 Fundamental definitions and identities

**Definition 1.1** (Complex number). A complex number is an expression of the form  $z = x + iy$ , where  $x$  and  $y$  are real numbers.

**Definition 1.2.** Every complex number  $z \neq 0$  has a multiplicative inverse given by

$$\frac{1}{z} = \frac{x - iy}{x^2 + y^2}.$$

**Definition 1.3** (Modulus). The modulus of a complex number  $z = x + iy$  is the length of the vector  $(x, y)$ , and is denoted  $|z|$ .

$$|z| = \sqrt{x^2 + y^2}.$$

**Proposition 1.4.** For  $z, w \in \mathbb{C}$ , it follows from the triangle inequality that

$$\begin{aligned} |z + w| &\leq |z| + |w| \\ |z - w| &\geq |z| - |w| \end{aligned}$$

**Definition 1.5** (Multiplication).  $(x + iy)(u + iv) = xu - yv + i(xv + yu)$ .

**Definition 1.6** (Complex conjugate). The complex conjugate of a complex number  $z = x + iy$  is defined to be  $\bar{z} = x - iy$ .

**Proposition 1.7.** For  $z, w \in \mathbb{C}$ , the following identities hold:

$$\begin{aligned} \bar{\bar{z}} &= z \\ \overline{z + w} &= \bar{z} + \bar{w} \\ \overline{z\bar{w}} &= \bar{z}w \\ \overline{z\bar{w}} &= \bar{z}w \\ |z| &= |\bar{z}| \\ |z|^2 &= z\bar{z} \\ |zw| &= |z||w| \end{aligned}$$

**Proposition 1.8.** The real and imaginary parts of  $z$  can be recovered from  $z$  by

$$\begin{aligned} \operatorname{Re} z &= (z + \bar{z})/2 \\ \operatorname{Im} z &= (z - \bar{z})/2i \end{aligned}$$

**Lemma 1.9** (Triangle inequality in  $\mathbb{R}^n$ ). Suppose  $a, b \in \mathbb{R}^n$ , with  $|a|$  the distance from  $a$  to 0 under the euclidean metric. Then

$$|a + b| \leq |a| + |b|.$$

*Proof:* If dot product of two vectors is zero, they are LI. Prove basis exists such that each vector dotted with all vectors in basis is zero (use nullity potentially). if  $a, b$  vectors such that  $b \cdot a = 0$ , then  $a \cdot (a + b) = a \cdot a$ . If  $|a + b| < |a|$  then  $a \cdot (a + b) < a \cdot a$ , so  $|a + b| \geq |a|$ .  $|a|, |b|$  are both geq than magnitude of their sides made of a scalar multiple of  $a + b$ .  $\square$

**Proposition 1.10.** Let  $a, b \in \mathbb{C}$ . Then

$$|a + b|^2 = |a|^2 + |b|^2 + a\bar{b} + b\bar{a} = |a|^2 + |b|^2 + 2\operatorname{Re} a\bar{b}.$$

**Lemma 1.11** (Triangle inequality in  $\mathbb{C}$ ). For  $x, y \in \mathbb{C}$ ,  $|x + y| \leq |x| + |y|$ .

*Proof:* Suppose  $u, v \in \mathbb{R}$ . Then

$$|u + iv| = \sqrt{u^2 + v^2} \geq \sqrt{u^2} = |u| \geq u.$$

Therefore  $\operatorname{Re} x + y \leq |x + y|$  and

$$2\operatorname{Re} x\bar{y} \leq 2|x\bar{y}| = 2|xy| = 2|x||y|$$

Because  $(|x| + |y|)^2 = |x|^2 + |y|^2 + 2|x||y|$ , it follows from proposition 1.10 that  $(|x| + |y|)^2 \leq (|x| + |y|)^2$ , and therefore  $|x + y| \leq |x| + |y|$ .  $\square$

**Definition 1.12** (Cauchy's inequality).

$$\left| \sum_{i=1}^n a_i b_i \right|^2 \leq \sum_{i=1}^n |a_i|^2 + \sum_{i=1}^n |b_i|^2$$

## 1.2 Polar representation

**Definition 1.13** (Polar representation). The polar representation of a complex number  $z = x + iy$  is

$$re^{i\theta} = r(\cos \theta + i \sin \theta).$$

Here  $r = |z|$ . The *argument* of  $z$  is a multivalued function of  $\theta$ , with

$$\arg z \in \{\theta + 2\pi k \mid k \in \mathbb{Z}\}.$$

The principle value of  $\arg z$  denoted  $\text{Arg } z$  is the unique member of  $\arg z$  such that  $-\pi < \text{Arg } z \leq \pi$ .

**Definition 1.14** (de Moivre's formulae). The identities obtained by equating the imaginary and real parts of the expansions of  $e^{in\theta}$  and  $(e^{i\theta})^n$  are known as de Moivre's formulae, e.g.

$$\begin{aligned} e^{2i\theta} &= (e^{i\theta})^2 \\ \cos 2\theta + i \sin 2\theta &= \cos^2 \theta + 2i \cos \theta \sin \theta - \sin^2 \theta \\ \cos 2\theta &= \cos^2 \theta - \sin^2 \theta \\ \sin 2\theta &= 2 \cos \theta \sin \theta \end{aligned}$$

**Definition 1.15** ( $n$ th root). A number  $z \in \mathbb{C}$  is the  $n$ th root of  $w \in \mathbb{C}$  if  $z^n = w$ . If  $w = \rho e^{i\varphi} \neq 0$ , then the  $n$ th roots of  $w$  are

$$\rho^{1/n} e^{i\varphi/n + 2\pi k/n}, \quad k = 0, 1, \dots, n-1.$$

This is equivalent to multiplying  $\rho^{1/n} e^{i\varphi/n}$  by the  $n$ th roots of unity, i.e. all  $n$ th roots of 1.

## 1.3 Exp, log, and power functions

**Definition 1.16** (Extended complex plane). The extended complex plane is the complex plane together with the point at infinity, denoted  $\mathbb{C}^* = \mathbb{C} \cup \{\infty\}$ .

**Proposition 1.17.** If  $z \in \mathbb{C}$  with  $z = x + iy$  then

$$e^z = e^x e^{iy} = e^x (\cos y + i \sin y).$$

## 2 Analytic Functions

**Remark.** Going forward, if a function's domain and codomain are not specified, the function is from  $\mathbb{C}$  to  $\mathbb{C}$ .

### 2.1 Limits

**Definition 2.1** (Limits). If the limit of  $f(z)$  as  $z$  approaches  $z_0$  is  $w_0$ , this means that for all  $\epsilon \in \mathbb{R}^+$ , there exists  $\delta \in \mathbb{R}^+$  such that

$$0 < |z - z_0| < \delta \Rightarrow |f(z) - w_0| < \epsilon.$$

This is written as  $\lim_{z \rightarrow z_0} f(z) = w_0$ . If the domain or range of the function we are taking the limit of is  $\mathbb{R}^n$ , the definition remains the same and uses the euclidean metric.

**Lemma 2.2.** The limit of a function is unique.

*Proof:* Suppose  $f : \mathbb{C} \rightarrow \mathbb{C}$  a function and that  $\lim_{z \rightarrow z_0} f(z) = w_0$  and  $\lim_{z \rightarrow z_0} f(z) = w_1$  with  $w_0 \neq w_1$ . Because  $w_0 \neq w_1$ ,  $|w_0 - w_1| = L > 0$ . If we take  $\epsilon = L/2$ , there exists  $\delta > 0$  such that  $|z - z_0| < \delta \Rightarrow |f(z) - w_0| < L/2 \wedge |f(z) - w_1| < L/2$ . Because  $(z - w_1) + (w_0 - z) = w_0 - w_1$ , by the triangle inequality  $|w_0 - w_1| \leq |f(z) - w_0| + |f(z) - w_1| = L$ , a contradiction.  $\square$

**Theorem 2.3.** Suppose  $f(z) = u(x, y) + iv(x, y)$ ,  $z = x + iy$ , and that  $z_0 = x_0 + iy_0$  and  $w_0 = u_0 + iv_0$ . Then  $\lim_{z \rightarrow z_0} f(z) = w_0$  iff

$$\lim_{(x,y) \rightarrow (x_0,y_0)} u(x, y) = u_0 \text{ and } \lim_{(x,y) \rightarrow (x_0,y_0)} v(x, y) = v_0. \quad (1)$$

*Proof:* Suppose  $\lim_{z \rightarrow z_0} f(z) = w_0$ . Then for all  $\epsilon > 0$  there exists  $\delta > 0$  such that

$$\begin{aligned} |(x - x_0) + i(y - y_0)| &= \sqrt{(x - x_0)^2 + (y - y_0)^2} < \delta \Rightarrow \\ |u(x, y) - u_0 + i(v(x, y) - v_0)| &= \sqrt{(u(x, y) - u_0)^2 + (v(x, y) - v_0)^2} < \epsilon. \end{aligned}$$

Because  $\sqrt{(u(x, y) - u_0)^2} \leq \sqrt{(u(x, y) - u_0)^2 + (v(x, y) - v_0)^2}$ ,

$$\sqrt{(x - x_0)^2 + (y - y_0)^2} < \delta \Rightarrow \sqrt{(u(x, y) - u_0)^2} < \epsilon.$$

Therefore wlog  $\lim_{(x,y) \rightarrow (x_0,y_0)} u(x, y) = u_0$  and  $\lim_{(x,y) \rightarrow (x_0,y_0)} v(x, y) = v_0$ .

Suppose  $\lim_{(x,y) \rightarrow (x_0,y_0)} u(x, y) = u_0$  and  $\lim_{(x,y) \rightarrow (x_0,y_0)} v(x, y) = v_0$ . Then for all  $\epsilon > 0$  there exists  $\delta_1, \delta_2 > 0$  such that

$$\begin{aligned} \sqrt{(x - x_0)^2 + (y - y_0)^2} < \delta_1 &\Rightarrow \sqrt{(u(x, y) - u_0)^2} < \epsilon/2, \\ \sqrt{(x - x_0)^2 + (y - y_0)^2} < \delta_1 &\Rightarrow \sqrt{(v(x, y) - v_0)^2} < \epsilon/2. \end{aligned}$$

If  $0 < \delta < \delta_1, \delta_2$ , it follows from the triangle inequality, the definition of  $f$ , and the definition of modulus that

$$|z - z_0| < \delta \Rightarrow |f(z) - w_0| < \epsilon.$$

Thus  $\lim_{z \rightarrow z_0} f(z) = w_0$ . □

**Remark.** Going forward, for  $x, y \in \mathbb{R}^n$ ,  $d(x, y)$  refers to the euclidean metric.

**Theorem 2.4.** Suppose that

$$\lim_{z \rightarrow z_0} f(z) = w_0 \text{ and } \lim_{z \rightarrow z_0} F(z) = W_0.$$

Then the following is true:

$$\begin{aligned} \lim_{z \rightarrow z_0} [f(z) + F(z)] &= w_0 + W_0, \\ \lim_{z \rightarrow z_0} [f(z)F(z)] &= w_0 W_0, \\ \lim_{z \rightarrow z_0} \frac{f(z)}{F(z)} &= \frac{w_0}{W_0}, \quad W_0 \neq 0. \end{aligned}$$

*Proof:* prove □

**Theorem 2.5.** If  $z_0$  and  $w_0$  are points in the  $z$  and  $w$  planes respectively, then the following properties hold:

$$\begin{aligned} \lim_{z \rightarrow z_0} f(z) = \infty &\Leftrightarrow \lim_{z \rightarrow z_0} \frac{1}{f(z)} = 0 \\ \lim_{z \rightarrow \infty} f(z) = w_0 &\Leftrightarrow \lim_{z \rightarrow 0} f\left(\frac{1}{z}\right) = w_0 \\ \lim_{z \rightarrow \infty} f(z) = \infty &\Leftrightarrow \lim_{z \rightarrow 0} \frac{1}{f(1/z)} = 0 \end{aligned}$$

*Proof:* prove □

## 2.2 Derivatives

**Definition 2.6** (Continuity). A function  $f$  is continuous at a point  $z_0$  if all three of the following conditions are satisfied:

- (a)  $\lim_{z \rightarrow z_0} f(z)$  exists.
- (b)  $f(z_0)$  exists.
- (c)  $\lim_{z \rightarrow z_0} f(z) = f(z_0)$ .

**Theorem 2.7.** *The composition of continuous functions is continuous.*

*Proof:* prove □

**Theorem 2.8.** *If a function  $f(z)$  is continuous and nonzero at a point  $z_0$ , then  $f(z) \neq 0$  throughout some neighborhood of that point*

*Proof:* prove □

**Theorem 2.9.** *If a function  $f$  is continuous throughout a region  $R$  that is both closed and bounded, there exists a nonnegative real number  $M$  and  $z' \in R$  such that*

$$\forall z \in R, |f(z)| \leq M$$

and

$$f(z') = M.$$

*Proof:* prove □

**Definition 2.10** (Derivative). Let  $f$  be a function whose domain of definition contains an  $\epsilon$ -neighborhood of  $z_0$ . The derivative of  $f$  at  $z_0$  is the limit

$$f'(z_0) = \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0}.$$

The function  $f$  is said to be differentiable at  $z_0$  if  $f'(z_0)$  exists. If we set  $\Delta z = z - z_0$ , we can write the definition as

$$f'(z_0) = \lim_{\Delta z \rightarrow 0} \frac{f(z_0 + \Delta z) - f(z_0)}{\Delta z}.$$

When using this form of the derivative, the subscript on  $z$  is often dropped and we introduce the number  $\Delta w = f(z + \Delta z) - f(z)$  so that the derivative becomes

$$f'(z_0) = \frac{dw}{dz} = \lim_{\Delta z \rightarrow 0} \frac{\Delta w}{\Delta z}.$$

**Proposition 2.11.** Because the derivative is a limit, if it exists it must be unique.

**Proposition 2.12.** If a function  $f : \mathbb{C} \rightarrow \mathbb{C}$  is differentiable at a point  $z_0 \in \mathbb{C}$ , then  $f$  is continuous at  $z_0$ .

**Proposition 2.13** (Differentiation formulas). Let  $c \in \mathbb{C}$  be a constant,  $z \in \mathbb{C}$  an independent variable,  $n \in \mathbb{Z}$ , and  $f$  a function from  $\mathbb{C} \rightarrow \mathbb{C}$  which is differentiable at  $z$ . These differentiation formulas can be derived from the definition of the derivative:

$$\begin{aligned} \frac{d}{dz} c &= 0 \\ \frac{d}{dz} z &= 1 \\ \frac{d}{dz} [cf(z)] &= cf'(z) \\ \frac{d}{dz} z^n &= nz^{n-1} \\ \frac{d}{dz} [f(z) + g(z)] &= f'(z) + g'(z) \\ \frac{d}{dz} f(z)g(z) &= f(z)g'(z) + f'(z)g(z) \\ \frac{d}{dz} \frac{f(z)}{g(z)} &= \frac{g(z)f'(z) - f(z)g'(z)}{[g(z)]^2} \end{aligned}$$

**Theorem 2.14** (Chain rule). *If  $f, g$  functions from  $\mathbb{C} \rightarrow \mathbb{C}$  differentiable at  $z \in \mathbb{C}$ , then*

$$\frac{d}{dz} g \circ f(z) = g' \circ f(z) \cdot f'(z).$$

## 2.3 Cauchy-Riemann equations

**Theorem 2.15.** Suppose that  $f(z) = u(x, y) + iv(x, y)$  with  $z = x + iy$  and that  $f'(z)$  exists at a point  $z_0 = x_0 + iy_0$ . Additionally, let  $u_x, v_x, u_y, v_y$  be the partial derivatives of the component functions of  $f$  with respect to  $x$  and  $y$  at  $x_0, y_0$ . Then the first order partial derivatives of  $u$  and  $v$  exist at  $x_0, y_0$ , and they must satisfy the Cauchy-Riemann equations

$$u_x = v_y, \quad u_y = -v_x$$

at that point.

*Proof:* prove □

**Remark.**  $1/i = -i$ .

**Corollary 2.16.**  $f'(z_0) = u_x + iv_x = v_y - iu_y$ .

**Theorem 2.17.** Let the function  $f(z) = u(x, y) + iv(x, y)$  be defined throughout some  $\epsilon$ -neighborhood of a point  $z_0 = x_0 + iy_0$ , and suppose that:

- (a) The first-order partial derivatives of the functions  $u$  and  $v$  with respect to  $x$  and  $y$  exist everywhere in the neighborhood.
- (b) Those partial derivatives are continuous at  $(x_0, y_0)$  and satisfy the Cauchy-Riemann equations at  $(x_0, y_0)$ .

Then  $f'(z_0)$  exists.

*Proof:* prove □

**Theorem 2.18.** Let the function  $f(z) = u(r, \theta) + iv(r, \theta)$  be defined throughout some  $\epsilon$ -neighborhood of a nonzero point  $z_0 = r_0 \exp(i\theta_0)$ , and suppose that

- (a) The first order partial derivatives of the function  $u$  and  $v$  with respect to  $r$  and  $\theta$  exist everywhere in the neighborhood;
- (b) Those partial derivatives are continuous at  $(r_0, \theta_0)$  and satisfy the polar form of the Cauchy Riemann equations.

Then  $f'(z_0)$  exists, its value being  $f'(z_0) = \exp(i\theta_0)(u_r + iv_r)$ .

*Proof:* prove □

## 2.4 Analytic and harmonic functions

**Definition 2.19** (Analytic function). A function  $f$  of the complex variable  $z$  is analytic at a point  $z_0$  if it has a derivative at each point in some neighborhood  $z_0$ . A function is analytic in an open set if it has a derivative everywhere in that set.

**Definition 2.20** (Entire function). An entire function from  $\mathbb{C} \rightarrow \mathbb{C}$  is a function that is analytic at each point in its domain.

**Remark.** Every polynomial is an entire function.

**Definition 2.21** (Singular point). If  $f : \mathbb{C} \rightarrow \mathbb{C}$  is a function not analytic at a point  $z_0$ , but analytic at some point in every neighborhood of  $z_0$ , then  $z_0$  is called a singular point.

**Proposition 2.22.** If two functions  $P$  and  $Q$  are analytic in a domain  $D$ , their sum and product are analytic. Their quotient is analytic in  $D$  provided the denominator is nonzero in  $D$ .

**Proposition 2.23.** The composition of two analytic functions is analytic.

**Theorem 2.24.** If  $f'(z) = 0$  everywhere in a domain  $D$ , then  $f(z)$  must be constant throughout  $D$ .

**Definition 2.25** (Harmonic). A real-valued function  $H$  of two real variables  $x$  and  $y$  is said to be harmonic in a given domain of the  $xy$  plane if, throughout that domain, it has continuous partial derivatives of the first and second order, and satisfies

$$H_{xx} + H_{yy} = 0.$$

**Theorem 2.26.** If a function  $f(z) = u(x, y) + iv(x, y)$  is analytic in a domain  $D$ , then its component functions  $u$  and  $v$  are harmonic in  $D$ .

**Theorem 2.27.** A function  $f(z) = u(x, y) + iv(x, y)$  is analytic in a domain  $D$  iff  $v$  is the harmonic conjugate of  $u$ .

### 3 Elementary functions

**Definition 3.1** (Branch). A branch of a multiple-valued function  $f$  is any single-valued function  $F$  that is analytic in some domain at each point  $z$  of which the value  $F(z)$  is one of the values of  $f$ .

**Definition 3.2** (Complex exponents). When  $z \neq 0$  and the exponent  $c$  is any complex number, the function  $z^c$  is defined by means of the equation

$$z^c = e^{c \log z}.$$

**Definition 3.3** (Sin and Cos).

$$\begin{aligned}\sin x &= \frac{e^{ix} - e^{-ix}}{2i} \\ \cos x &= \frac{e^{ix} + e^{-ix}}{2}\end{aligned}$$

## 4 Integrals

### 4.1 Derivatives and contours

**Definition 4.1** (Derivative). Let  $w(t) = u(t) + iv(t)$  be a complex-valued function of a real variable, where the functions  $u(t)$  and  $v(t)$  are real valued functions of a real variable. Then the derivative of  $w(t)$  with respect to  $t$  is

$$\frac{d}{dt}w(t) = \frac{d}{dt}u(t) + i \frac{d}{dt}v(t).$$

**Definition 4.2** (Definite integral for function of a real variable). When  $w(t)$  is a complex-valued function of a real variable  $t$ , written

$$w(t) = u(t) + iv(t),$$

where  $u$  and  $v$  are real-valued, the definite integral of  $w(t)$  over an interval  $a \leq t \leq b$  is

$$\int_a^b w(t)dt = \int_a^b u(t)dt + i \int_a^b v(t)dt,$$

Provided the integrals on the left exist.

**Remark.** This is analagous to derivatives of vector functions in calculus, where the definite integral of a function  $f : \mathbb{R} \rightarrow \mathbb{R}^n$  is a vector in  $\mathbb{R}^n$ .

**Definition 4.3** (Arc). A set of points  $z = (x, y)$  in the complex plane is said to be an arc if

$$x = x(t), \quad y = y(t), \quad a \leq t \leq b$$

where  $x$  and  $y$  are continuous functions of the real parameter  $t$ . An arc  $C$  is called a simple arc, or a Jordan arc, if it does not cross itself. When the arc is simple except for the fact that  $z(b) = z(a)$ , we say that  $C$  is a simple closed curve. Such a curve is positively oriented when it is in the counterclockwise direction.

**Definition 4.4** (Smooth arc). A smooth arc  $z = z(t)$  defined on  $a \leq t \leq b$  has continuous first derivatives on its domain  $a \leq t \leq b$  which are nonzero on  $a < t < b$ .

**Definition 4.5** (Contour). A contour, or piecewise smooth arc, is an arc consisting of a finite number of smooth arcs joined end to end. When only the initial and final values of a contour  $C$  are the same, we say  $C$  is a simple closed contour.

**Theorem 4.6** (Jordan curve theorem). *The points on any simple closed contour  $C$  are boundary points of two distinct domains. One of these domains is the interior of  $C$ , and is bounded. The other is the exterior of  $C$ , and is unbounded.*

## 4.2 Contour integrals

Suppose a contour  $C$  is represented by the function  $z : \mathbb{R} \rightarrow \mathbb{C}$  on the interval  $(a \leq t \leq b)$ . If  $f : \mathbb{C} \rightarrow \mathbb{C}$  a function, and  $f[z(t)]$  is piecewise continuous on the interval  $a \leq t \leq b$ , the function  $f$  is piecewise continuous on  $C$ . We then define the contour integral of  $f$  along  $C$  as

$$\int_C f(z)dz = \int_a^b f[z(t)]z'(t)dt.$$

**Proposition 4.7.** It follows from the properties of complex-valued functions of a real variable that

$$\begin{aligned}\int_C z_0 f(z)dz &= z_0 \int_C f(z)dz, \\ \int_C [f(z) + g(z)]dz &= \int_C f(z)dz + \int_C g(z)dz.\end{aligned}$$

**Remark.** prove statements of section 40, 41, 42

## 4.3 Contour integral other shit

**Lemma 4.8.** If  $w : \mathbb{R} \rightarrow \mathbb{C}$  is piecewise continuous on an interval  $a \leq t \leq b$ , then

$$\left| \int_a^b w(t)dt \right| \leq \int_a^b |w(t)|dt.$$

**Theorem 4.9.** Let  $C$  denote a contour of length  $L$ , and suppose that a function  $f : \mathbb{C} \rightarrow \mathbb{C}$  is continuous on  $C$ . If  $M$  is a nonnegative constant such that

$$|f(z)| \leq M,$$

for all points  $z$  on  $C$  at which  $f(z)$  is defined, then

$$\left| \int_C f(z)dz \right| \leq ML.$$

**Theorem 4.10.** Suppose that a function  $f : \mathbb{C} \rightarrow \mathbb{C}$  is continuous on domain  $D$ . The following statements are logically equivalent:

- (a)  $f$  has an antiderivative  $F$  throughout  $D$ .
- (b) The integrals of  $f$  along contours lying entirely in  $D$  and extending from any fixed point  $z_1$  to any fixed point  $z_2$  all have the same value.
- (c) The integrals around closed contours lying entirely in  $D$  are equal to zero.

**Theorem 4.11** (Cauchy-Goursat theorem).

If a function  $f : \mathbb{C} \rightarrow \mathbb{C}$  is analytic at all points interior to and on a simple closed contour  $C$ , then

$$\int_C f(z)dz = 0.$$

**Theorem 4.12.** If a function  $f : \mathbb{C} \rightarrow \mathbb{C}$  is analytic throughout a simply connected domain  $D$ , then

$$\int_C f(z)dz = 0$$

for every closed contour  $C$  lying in  $D$ .

**Remark.** Notice the lack of specificity that this contour is simple.

**Theorem 4.13.** Suppose that

- (a)  $C$  is a simple closed contour, described in the counterclockwise direction.
- (b)  $C_k$ ,  $k = 1, \dots, n$  are simple closed contours interior to  $C$ , all described in the clockwise direction, that are disjoint and whose interiors have no points in common.

If a function  $f$  is analytic on all of these contours and throughout the multiply connected domain consisting of the points inside  $C$  and exterior to each  $C_k$ , then

$$\int_C f(z)dz + \sum_{k=1}^n \int_{C_k} f(z)dz = 0.$$

**Corollary 4.14** (Principle of deformation of paths). Let  $C_1$  and  $C_2$  denote positively oriented simple closed contours, where  $C_1$  is interior to  $C_2$ . If a function  $f$  is analytic in the closed region consisting of these contours and all points between them, then

$$\int_{C_1} f(z)dz = \int_{C_2} f(z)dz.$$

**Theorem 4.15** (Cauchy integral formula). Let  $f : \mathbb{C} \rightarrow \mathbb{C}$  be analytic everywhere inside and on a simple closed contour  $C$ , taken in the positive sense. If  $z_0$  is any point interior to  $C$ , then

$$f(z_0) = \frac{1}{2\pi i} \int_C \frac{f(z)dz}{z - z_0}.$$

**Remark.** read 51-53

**Lemma 4.16.** Suppose that  $|f(z)| \leq |f(z_0)|$  at each point  $z$  in some neighborhood  $|z - z_0| < \epsilon$  in which  $f$  is analytic. Then  $f(z)$  has constant value  $f(z_0)$  throughout that neighborhood.

**Theorem 4.17.** If a function  $f$  is analytic and not constant in a given domain  $D$ , then  $|f(z)|$  has no maximum value in  $D$ . That is, there is no point  $z_0$  in the domain such that  $|f(z)| \leq |f(z_0)|$  for all points  $z \in D$ .

## 5 Sequences

### 5.1 Convergence

**Definition 5.1** (Convergence of sequences). A sequence  $(z_n)_{n=1}^{\infty}$  of complex numbers has a limit  $z$  if

$$\forall \epsilon > 0, \exists N \in \mathbb{N}, \forall n \in \mathbb{N}, (n > N \Rightarrow |z_n - z| < \epsilon)$$

When a sequence has a limit, it is said to converge.

**Theorem 5.2.** Suppose that  $z_n = x_n + iy_n$ . Then  $\lim_{n \rightarrow \infty} z_n = z$  iff

$$\lim_{n \rightarrow \infty} x_n = x, \quad \lim_{n \rightarrow \infty} y_n = y.$$

**Definition 5.3** (Convergence of series). An infinite series

$$\sum_{n=1}^{\infty} z_n = z_1 + z_2 + \dots$$

of complex numebtrs converges to the sum  $S$  if the sequence

$$S_N = \sum_{n=1}^N z_n$$

of partial sums converges to  $S$ . We then write

$$\sum_{n=1}^{\infty} z_n = S.$$

**Theorem 5.4.** Suppose that  $z_n = x_n + iy_n$  and  $S = X + iY$ . Then

$$\sum_{n=1}^{\infty} z_n = S \Leftrightarrow \sum_{n=1}^{\infty} x_n = X \text{ and } \sum_{n=1}^{\infty} y_n = Y.$$

**Corollary 5.5.** If a series of complex numbers converges, the  $n$ th term converges to zero as  $n$  tends to infinity.

## 5.2 Taylor series

**Theorem 5.6.** Suppose that a function  $f$  is analytic throughout a disk  $|z - z_0| < R_0$ , centered at  $z_0$  and with radius  $R_0$ . Then  $f(z)$  has the power series representation

$$f(z) = \sum_{n=0}^{\infty} a_n (z - z_0)^n \quad (|z - z_0| < R_0),$$

where

$$a_n = \frac{f^{(n)}(z_0)}{n!} \quad n \in \mathbb{Z}^+.$$

**Definition 5.7** (Maclaurin series). A Maclaurin series is a Taylor series centered at  $z_0 = 0$ .

**Theorem 5.8.** Suppose that a function  $f$  is analytic throughout an annular domain  $R_1 < |z - z_0| < R_2$ , centered at  $z_0$ , and let  $C$  denote any positively oriented simple closed contour around  $z_0$  and lying in that domain. Then, at each point in the domain,  $f(z)$  has the series representation

$$f(z) = \sum_{n=0}^{\infty} a_n (z - z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z - z_0)^n} \quad (R_1 < |z - z_0| < R_2).$$

where

$$a_n = \frac{1}{2\pi i} \int_C \frac{f(z) dz}{(z - z_0)^{n+1}} \quad n = 0, 1, \dots,$$

and

$$b_n = \frac{1}{2\pi i} \int_C \frac{f(z) dz}{(z - z_0)^{-n+1}} \quad n = 1, 2, \dots$$

## 5.3 Absolute and uniform convergence

**Definition 5.9** (Absolute convergence). A series of complex numbers converges absolutely if the series of absolute values of those numbers converges.

**Theorem 5.10.** If a power series

$$\sum_{n=0}^{\infty} a_n (z - z_0)^n$$

converges when  $z = z_1$  with  $z_1 \neq z_0$ , then it is absolutely convergent at each point  $z$  in the open disk  $|z - z_0| < R_1$  where  $R_1 = |z_1 - z_0|$ .

**Remark.** The greatest circle centered at  $z_0$  such that the above series converges is called the circle of convergence.

**Remark.** when proving this, go over uniform convergence.

**Theorem 5.11.** A power series

$$\sum_{n=0}^{\infty} a_n (z - z_0)^n$$

represents a continuous function  $S(z)$  at each point inside its circle of convergence  $|z - z_0| = R$ .

## 5.4 Integration and differentiation of power series

**Theorem 5.12.** Let  $C$  denote any contour interior to the circle of convergence of the power series

$$S(z) = \sum_{n=0}^{\infty} a_n (z - z_0)^n, \tag{2}$$

and let  $g(z)$  be any function that is continuous on  $C$ . The series formed by multiplying each term of the power series by  $g(z)$  can be integrated term by term over  $C$ , i.e.

$$\int_C g(z) S(z) dz = \sum_{n=0}^{\infty} a_n \int_C g(z) (z - z_0)^n dz.$$

**Corollary 5.13.** The sum  $S(z)$  of power series in equation 2 is analytic at each point  $z$  interior to the circle of convergence of that series.

**Theorem 5.14.** *The power series in equation 2 can be differentiated term by term, i.e. at each point  $z$  interior to the circle of convergence of that series,*

$$S'(z) = \sum_{n=1}^{\infty} n a_n (z - z_0)^{n-1}.$$

**Theorem 5.15.** *If a series*

$$\sum_{n=0}^{\infty} a_n (z - z_0)^n$$

*converges to  $f(z)$  at all points interior to some circle  $|z - z_0| = R$ , then it is the Taylor series expansion for  $f$  in powers of  $z - z_0$ .*

**Theorem 5.16.** *If a series*

$$\sum_{n=-\infty}^{\infty} c_n (z - z_0)^n = \sum_{n=0}^{\infty} a_n (z - z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z - z_0)^n}$$

*Converges to  $f(z)$  at all points in some annular domain about  $z_0$ , then it is the Laurent series expansion for  $f$  in powers of  $z - z_0$  for that domain.*
